

A complete analysis of peptide microarray binding data using the pepStat framework

Greg Imholte*, Renan Sauteraud†, Mike Jiang‡ and Raphael Gottardo§

December 3, 2013

This document present a full analysis, from reading the data to displaying the results that makes use of all the packages we developped for peptide microarray.

1 Introduction

The **pepStat** package offers a complete analytical framework for the analysis of peptide microarray data. It includes a novel normalization method to remove non-specific peptide binding activity of antibodies, a data smoothing reducing step to reduce background noise, and subject-specific positivity calls.

1.1 Requirements

The **pepStat** package requires **GSL**, an open source scientific computing library. This library is freely available at <http://www.gnu.org/software/gsl/>.

In this vignette, we make use of the samples and examples available in the data package **PEP.db**.

2 Generating a peptideSet

```
library(PEP.db)
library(pepStat)
```

2.1 Reading in .gpr files

The reading function, **makePeptideSet**, takes a path as its argument and parses all the *.gpr* files in the given directory. Alternatively, one may specify a character vector of paths to individual *.gpr* files.

By default channels F635 Median and B635 Median are collected, and the 'normexp' method of the **backgroundCorrect** function in the **limma** package corrects probe intensities for background fluorescence. Other methods may be selected, see documentation.

```
mapFile <- system.file("extdata/mapping.csv", package = "PEP.db")
dirToParse <- system.file("extdata/gpr_samples", package = "PEP.db")
pSet <- makePeptideSet(files = NULL, path = dirToParse,
                      mapping.file = mapFile, log=TRUE)
```

While optional, it is strongly recommended to provide a **mapping.file** giving annotations data for each slide, such as treatment status or patient information. If provided, the **mapping.file** should be a **.csv** file. It must include columns labeled **filename**, **ptid**, and **visit**. Elements in column **filename** must correspond to the filenames of slides to be read in, without the *.gpr* extension. Column **ptid** is a subject or slide identifier. Column **visit** indicates a case or control condition, such as pre/post vaccination, pre/post infection, or healthy/infected status. Control conditions must be labelled *pre*, while case conditions must be labelled *post*. Alternatively, one may input a **data.frame** satisfying the same requirements.

This minimal information is required by **pepStat**'s functions further in the analysis. Any additional information (column) will be retained and can be used as a grouping variable.

If no mapping file is included, the information will have to be added later on to the **peptideSet** object.

For our example, we use a toy dataset of 8 samples from 4 patients and we are interested in comparing the antibody binding in placebo versus vaccinated subjects.

```
read.csv(mapFile)

##  filename ptid visit treatment
## 1      f1_1    1   Pre  PLACEBO
## 2      f1_2    1  Post  PLACEBO
## 3      f2_1    2   Pre  PLACEBO
## 4      f2_2    2  Post  PLACEBO
## 5      f3_1    3   Pre  VACCINE
## 6      f3_2    3  Post  VACCINE
## 7      f4_1    4   Pre  VACCINE
## 8      f4_2    4  Post  VACCINE
```

2.2 Additional arguments

The empty spots should be listed in order to background correct the intensities. It is also useful to remove the controls when reading the data. Here we have the JPT controls, human Ig (A, E and M) and dye controls.

```
pSetNoCtrl <- makePeptideSet(files = NULL, path = dirToParse,
                             mapping.file = mapFile, log = TRUE,
                             rm.control.list = c("JPT-control", "Ig", "Cy3"),
                             empty.control.list= c("empty", "blank control"))
```

2.3 Visualize slides

We include two plotting functions to detect possible spatial slide artifacts. Since the full plate is needed for this visualization, the functions will only work with `rm.control.list` and `empty.control.list` set to `NULL` in `makePeptideSet`.

```
plotArrayImage(pSet, array.index = 1)
```

Sample Name: f1_1

```
plotArrayResiduals(pSet, array.index = 1, smooth = TRUE)
```

Smoothed Residuals for Sample Name f1_1

3 Adding peptide informations

At this point, the peptideSet contain only the peptide sequences and the associated background corrected intensities. To continue with the analysis, we need to add the position information, as well as physicochemical properties of the peptides summarized by their z-scales.

The slides used in this example are the envelope of HIV-1 and peptide collections are available for this in our PEP.db package (please refer to the vignette and `?pep_hxb2` for more information). However, we will pretend that this is not the case to show an example of how to build a custom peptide collection.

3.1 Creating a custom peptide collection

Here, we load a data.frame that contains the peptides used on the array as well as their start and end coordinates.

```
peps <- read.csv(system.file("extdata/pep_info.csv", package = "PEP.db"))
head(peps)
```

```
##   start end      peptide
## 1     1  16 MRVKETQMNWPNLWK
## 2     1  16 MRVMGIQKNYPLLWR
## 3     1  16 MRVMGIQRNCQHLWR
## 4     1  16 MRVKGIRKNYQHLWR
## 5     1  16 MRVRGILRNWQQWWI
## 6     1  16 MRVRGIERNYQHLWR
```

We first create a `RangedData` object with the available information. The region of interest is the envelope of the virus so we add the space information to the object.

```
rd <- RangedData(ranges=IRanges(start = peps$start, end=peps$end),
                 peptide=peps$peptide, space="gp160")
```

The z-scores are added afterward, using the `create_db` function.

```
pep_custom <- create_db(rd=rd)
```

3.2 Summarize the information

The function `summarizePeptides` summarizes within-slide replicates by either their mean or median. Additionally, with the newly constructed peptide collection, peptides positions and annotations can be passed on to the existing `peptideSet`.

```
psSet <- summarizePeptides(pSet, summary = "mean", position = pep_custom)

## Some peptides have no match in the RangedData object rownames and are removed from
the peptideSet!
```

Now that all the required information is available, we can proceed with the analysis.

4 Normalization

The primary goal of the data normalization step is to remove non-biological source of bias and increase the comparability of true positive signal intensities across slides. The method developed for this package uses physiochemical properties of individual peptides to model non-specific antibody binding to arrays.

```
pnSet <- normalizeArray(psSet)
```

An object of class `peptideSet` containing the corrected peptides intensities is returned.

5 Data smoothing

The optional data smoothing step takes advantage of the overlapping nature of the peptides on the array to remove background noise caused by experimental variation. It is likely that two overlapping peptides will share common binding signal, when present. `pepStat` use a sliding mean technique to borrow strength across neighboring peptides and to reduce signal variability. This statistic increases detection of binding *hotspots* that noisy signals might otherwise obscure. Peptides are smoothed according to their sequence alignment position, taken from `position(pSet)`.

```
psmSet <- slidingMean(pnSet, width = 9)
```

6 Making calls

The final step is to make the positivity calls. The function `makeCalls` automatically uses information provided in the mapping file, accessed via `pData(pSet)`. It detects whether samples are paired or not. If samples are paired, POST intensities are subtracted from PRE intensities, then thresholded. Otherwise, PRE samples are averaged, and then subtracted from POST intensities. These corrected POST intensities are thresholded.

The `freq` argument controls whether we return the percentage of responders against each peptide, or a matrix of subject specific call. When `freq` is `TRUE`, we may supply a `group` variable from `pData(psmSet)` on which we split the frequency calculation.

```
V_calls <- makeCalls(psmSet, freq = TRUE, group = "treatment",
                    cutoff = .1, method = "FDR", verbose = TRUE)

## You have paired PRE/POST samples

## The selected threshold T is 0.7502
```

The function automatically selected an appropriate FDR threshold.

7 Summary

Here we showcase a quick analysis of peptide microarray data for HIV-1 gp160. This displays the minimal amount of code required to go from raw data file to antibody binding positivity call.

```
mapFile <- system.file("extdata/mapping.csv", package = "PEP.db")
dirToParse <- system.file("extdata/gpr_samples", package = "PEP.db")
ps <- makePeptideSet(files = NULL, path = dirToParse,
                     mapping.file = mapFile, log = TRUE,
                     rm.control.list = c("JPT-control", "Ig", "Cy3"),
                     empty.control.list = c("empty", "blank control"))

data(pep_hxb2)
ps <- summarizePeptides(ps, summary = "mean", position = pep_hxb2)

## Some peptides have no match in the RangedData object rownames and are removed from
the peptideSet!

ps <- normalizeArray(ps)
ps <- slidingMean(ps, width = 9)
V_calls <- makeCalls(ps, freq = TRUE, group = "treatment",
                    cutoff = .1, method = "FDR", verbose = TRUE)

## You have paired PRE/POST samples
```
